

**REMARKS**

This Amendment is filed in response to the FINAL Office action mailed August 26, 2005. All objections and rejections are traversed.

Claims 1 to 4 and 9 to 35 are in the application and currently pending.

Claims 26, 27, 33, and 34 are currently amended to overcome objections.

**Allowable Subject Matter**

Claims 26 and 33 were objected to as being dependent upon a rejected base claim.

Claims 26 and 33 have been amended into independent form and are believed to be allowable.

**35 U.S.C. §112**

At page 2 of the Office Action, claims 27 and 34 were rejected under 35 U.S.C. §112 as failing to comply with the written description requirement and as being indefinite.

Claims 27 and 34 are amended to overcome the rejection.

**35 U.S.C. §103**

At page 3 of the Office action claims 1-3 and 9-16 were rejected under 35 U.S.C. § 103 as being unpatentable over Martin et al., US Patent No. 6,765,927, issued July 20, 2004, hereinafter Martin, in view of “Real-Time Streaming Protocol”, Request for comment 2326, April 1998, hereinafter RFC 2326.

The present invention, as set forth in representative claim 1, comprises in aprt:

1. An intermediate network device for use within a computer network having a server configured to provide one or more data streams to a client, each stream having a corresponding bandwidth, the network device comprising:

means for determining network traffic characteristics sufficient to identify a stream from the server to the client;

*a packet classification engine for snooping on Real Time Streaming Protocol (RTSP) messages for determining the bandwidth of the stream; and*

a resource reservation protocol (RSVP) transmitter proxy configured to reserve resources within the computer network on behalf of the server for allocation to the stream.

By way of background, Martin describes a Resource Reservation protocol (RSVP) host proxy service. A switch provides the RSVP proxy service for an RSVP-unaware source. The RSVP-unaware source transmits packets with headers and the switch reads the headers for information to use in a RSVP protocol.

RFC 2326 describes the Real Time Streaming Protocol (RTSP). RTSP is an application-level protocol for control over the delivery of data with real-time properties.

Applicant respectfully urges that Martin and RFC 2326 do not show Applicant's novel *a packet classification engine for snooping on Real Time Streaming Protocol (RTSP) messages for determining the bandwidth of the stream.*

Nowhere does Martin determine the *bandwidth of the stream* from the headers because the headers do not contain information to determine the actual bandwidth needed. In further detail, the Tspec header in Martin describes the resources that should be reserved. (Col. 5, lines 23-30).

The Examiner argues that Martin at Col.3, lines 23-26 and Col. 5, lines 1-5 describes a packet classification engine for determining the bandwidth of the stream.

Col. 3, lines 23-26 states:

“Edge switch 140 receives the data packet, determines that the data packet meets RSVP sender host proxy criteria, generates an RSVP Path message in accordance with an RSVP sender host function, modifies certain fields of the RSVP Path message if required in accordance with an RSVP router function, and transmits the RSVP Path message on backbone network 130.”

Col. 5, lines 1-5 states:

“RSVP Path message 330 includes an RSVP common header identifying the message as a Path message and an RSVP object including the contents of the Path message. The contents of the Path message include a Sender TSPEC describing the flow the sender expects to generate and an ADSPEC. The Sender TSPEC traverses the flowpath from the RSVP sender to the RSVP receiver without modification, whereas the ADSPEC may be modified by switches along the flowpath to indicate the availability of QoS control services and parameters required for QoS control services to operate correctly.”

In reference to the above statements, Martin is silent concerning determining the actual bandwidth of the stream. The cited art describes using a switch to determine an approximate bandwidth based on RSVP request messages. In sharp contrast, Applicant's invention determines the actual bandwidth as determined by snooping. Furthermore, Applicant's invention prevents too much bandwidth from being reserved, or congestion developing because not enough bandwidth is reserved.

The Examiner argues that RFC 2326 at abstract and two paragraphs above Appendix A describes stream control.

Abstract states:

"The Real Time Streaming Protocol, or RTSP, is an application-level protocol for control over the delivery of data with real-time properties. RTSP provides an extensible framework to enable controlled, on-demand delivery of real-time data, such as audio and video. Sources of data can include both live data feeds and stored clips. This protocol is intended to control multiple data delivery sessions, provide a means for choosing delivery channels such as UDP, multicast UDP and TCP, and provide a means for choosing delivery mechanisms based upon RTP (RFC 1889)."

Two paragraphs above Appendix A states:

"Stream issues:

RTSP only provides for stream control. Stream delivery issues are not covered in this section, nor in the rest of this memo. RTSP implementations will most likely rely on other protocols such as RTP, IP multicast, RSVP and IGMP, and should address security considerations brought up in those and other applicable specifications."

"12.6 Bandwidth

The Bandwidth request header field describes the estimated bandwidth

available to the client, expressed as a positive integer and measured in bits per second. The bandwidth available to the client may change during an RTSP session, e.g., due to modem retraining.”

In reference to the above statements, RFC 2326 is silent concerning using the messages to determine the actual bandwidth. The above statements describe reading header fields to estimate bandwidth. Applicant’s invention claims determining the bandwidth based on the actual messages to find the actual bandwidth necessary to send the messages.

In Martin or RFC 2326 the estimate of bandwidth can be inefficient. With the estimate based on message requests, there is a strong possibility too much bandwidth may be reserved when messages are not sent. Additionally, if enough bandwidth is not reserved, congestion can occur as messages are sent.

Applicant respectfully urges that the Martin patent and RFC 2326 either taken singly or taken in combination are legally precluded from rendering the presently claimed invention obvious under 35 U.S.C. §103 because of the absence in each of the cited patents of Applicant’s claimed novel *a packet classification engine for snooping on Real Time Streaming Protocol (RTSP) messages for determining the bandwidth of the stream.*

At page 7 of the Office Action claim 4 was rejected under 35 U.S.C. §103 as being unpatentable over Martin, in view of Resource ReSerVation Protocol (RSVP), RFC 2205.

Applicant respectfully notes that claim 4 is a dependent claim that depends from independent claim 1, which is believed to be in condition for allowance. Accordingly claim 4 is believed to be in condition for allowance.

At page 7 of the Office Action claims 17-19 were rejected under 35 U.S.C §103 as being unpatentable over Martin, in view of “Format of the RSVP DCLASS Object”, Request For Comments 2996, published November 2000, hereinafter RFC 2996.

The present invention, as set forth in representative claim 17 comprises in part:

17. An intermediate network device for use within a computer network having a server configured to provide one or more data streams to a client, each stream having a corresponding bandwidth, the intermediate network device comprising:

means for determining traffic characteristics sufficiently to identify a stream from the server to the client;

***means for determining the bandwidth of the stream;***

a resource reservation protocol (RSVP) transmitter proxy configured to reserve resources within the computer network on behalf of the server for allocation to the stream and to generate and send one or more RSVP Path messages on behalf of the server, the one or more RSVP Path messages containing the network traffic characteristics and the bandwidth of the stream, and means for obtaining a differentiated services codepoint (DSCP) value that is based on the bandwidth of the stream.

By way of background, RFC 2996 describes using a resource Reservation Protocol to handle request for Quality of Service. The system is based in a differentiated service (DS) network. Using RSVP with DS networks allows the RSVP message objects to carry Differential Service Code Points (DSCPs)

Applicant respectfully urges that Martin or RFC 2996 do not show Applicant's novel *means for determining the bandwidth of the stream*. Martin and RFC 2996 are silent concerning determining the actual bandwidth necessary from the RSVP messages.

Applicant respectfully urges that the Martin patent and RFC 2996 either taken singly or taken in combination are legally precluded from rendering the presently claimed invention obvious under 35 U.S.C. §103 because of the absence in each of the cited patents of Applicant's claimed novel *means for determining the bandwidth of the stream*.

At page 9 of the Office Action, claims 20-25, 27, 29-32, and 34 were rejected under 35 U.S.C. §103 as being unpatentable over Martin, in view of Merwe et al., "mmdump: A Tool for Monitoring Internet Multimedia Traffic", 2000, hereinafter Merwe.

The present invention, as set forth in representative claim 20 comprises in part:

20. A method for providing one or more data streams from a server to a client, each stream having a corresponding bandwidth, the method comprising:  
receiving a message from a client to a server,  
determining network traffic characteristics sufficient to identify a stream from the server to the client;

*determining the bandwidth of the stream*; and  
sending via a resource reservation protocol (RSVP) transmitter  
proxy, messages to nodes along a data path from the server to the client to  
reserve resources within the computer network on behalf of the server for  
allocation to the stream.

By way of background, Merwe describes a system using a Real Time Streaming Protocol (RTSP). The RTSP is used to set up and control the playback of streaming content across the internet. A client may issue a DESCRIBE command request for a particular media stream. The response from the server contains specific information about the stream, e.g., the encoding used, the clip length, and the average bit rate. Furthermore, the estimated bandwidth set up to send streaming content is determined by packet arrival times and a probe point.

Applicant respectfully urges that Martin and Merwe do not show Applicant's claimed novel *determining the bandwidth of the stream*. Applicant claims the bandwidth is determined based on the actual RSVP messages that will be sent. By determining the actual bandwidth, the system is more efficient. In contrast, Merwe only describes an estimated bandwidth based on packet arrival times and a probe point. Furthermore, Martin estimates the bandwidth on RSVP request messages. Neither Martin nor Merwe describe determining the bandwidth based on actual messages.

Applicant respectfully urges that the Martin patent and Merwe either taken singly or taken in combination are legally precluded from rendering the presently claimed invention obvious under 35 U.S.C. §103 because of the absence in each of the cited patents of Applicant's claimed novel *determining the bandwidth of the stream*.

At page 11 of the Office Action claims 28 and 35 were rejected under 35 U.S.C. §103 as being unpatentable over martin, in view of Merwe, and in further view of Gai et al, "RSVP Proxy – Internet Draft", hereinafter Gai.

Applicant respectfully notes that claims 28 and 35 are dependent claims that depend from independent claims, which are believed to be in condition for allowance. Accordingly claims 28 and 35 are believed to be in condition for allowance.

All independent claims are believed to be in condition for allowance.

All dependent claims are believed to be dependent from allowable independent claims, and therefore in condition for allowance.

Favorable action is respectfully solicited.

Please charge any additional fee occasioned by this paper to our Deposit Account No. 03-1237.

Respectfully submitted,
